

Cryptography, briefly

John Mitchell

802.11b slides from Dan Boneh

Cryptography

- ◆ Is
 - Tremendous tool
 - Basis for many security mechanisms
- ◆ Is not
 - The solution to all security problems
 - Secure unless implemented properly
 - Secure if used improperly

Basic Concepts in Cryptography

- ◆ Encryption scheme:
 - functions to encrypt, decrypt data
 - key generation algorithm
- ◆ Secret vs. public key
 - Public key: publishing key does not reveal key^{-1}
 - Secret key: more efficient; can have $key = key^{-1}$
- ◆ Hash function
 - map text to short hash; ideally, no collisions
- ◆ Signature scheme
 - functions to sign data and confirm signature

Cryptosystem

- ◆ A cryptosystem consists of five parts
 - A set P of plaintexts
 - A set C of ciphertexts
 - A set K of keys
 - A pair of functions
 - encrypt: $K \times P \rightarrow C$
 - decrypt: $K \times C \rightarrow P$
- such that for every key $k \in K$ and plaintext $p \in P$
- $$\text{decrypt}(k, \text{encrypt}(k, p)) = p$$
- OK def'n for now, but doesn't include key generation or prob encryption.

Primitive example: shift cipher

◆ Shift letters using mod 26 arithmetic

- Set P of plaintexts {a, b, c, ..., x, y, z}
- Set C of ciphertexts {a, b, c, ..., x, y, z}
- Set K of keys {1, 2, 3, ..., 25}
- Encryption and decryption functions

$$\text{encrypt}(\text{key}, \text{letter}) = \text{letter} + \text{key} \pmod{26}$$

$$\text{decrypt}(\text{key}, \text{letter}) = \text{letter} - \text{key} \pmod{26}$$

v Example

$$\text{encrypt}(3, \text{stanford}) = \text{vwqjruq}$$

Evaluation of shift cipher

◆ Advantages

- Easy to encrypt, decrypt
- Ciphertext does look garbled

◆ Disadvantages

- Not very good for long sequences of English words
 - Few keys – only 26 possibilities
 - Regular pattern
 - $\text{encrypt}(\text{key}, x)$ is same for all occurrences of letter x
 - can use letter-frequency tables, etc

Letter frequency in English

◆ Five frequency groups [Baker and Piper]

E has probability	0.12
TADINSHR have probability	0.06 - 0.09
DL have probability	~ 0.04
CUMWPGYFB have probability	0.015 - 0.028
VKIQZ have probability	< 0.01

Possible to break letter-to-letter substitution ciphers.

- 1400: Arabs did careful analysis of words in Koran
- 1500: realized that letter-frequency could break substitution ciphers

One-time pad

◆ Secret-key encryption scheme (symmetric)

- Encrypt plaintext by xor with sequence of bits
- Decrypt ciphertext by xor with same bit sequence

◆ Scheme for pad of length n

- Set P of plaintexts: all n-bit sequences
- Set C of ciphertexts: all n-bit sequences
- Set K of keys: all n-bit sequences
- Encryption and decryption functions

$$\text{encrypt}(\text{key}, \text{text}) = \text{key} \oplus \text{text} \quad (\text{bit-by-bit})$$

$$\text{decrypt}(\text{key}, \text{text}) = \text{key} \oplus \text{text} \quad (\text{bit-by-bit})$$

Evaluation of one-time pad

◆ Advantages

- Easy to compute encrypt, decrypt from key, text
- As hard to break as possible
 - This is an information-theoretically secure cipher
 - Given ciphertext, all possible plaintexts are equally likely, assuming that key is chosen randomly

◆ Disadvantage

- Key is as long as the plaintext
 - How does sender get key to receiver securely?

Idea can be combined with pseudo-random generators....

What is a "secure" cryptosystem?

◆ Idea

- If enemy intercepts ciphertext, cannot recover plaintext

◆ Issues in making this precise

- What else might your enemy know?
 - The kind of encryption function you are using
 - Some plaintext-ciphertext pairs from last year
 - Some information about how you choose keys
- What do we mean by "cannot recover plaintext"?
 - Ciphertext contains no information about plaintext
 - No efficient computation could make a reasonable guess

Information-theoretic security

◆ Remember conditional probability...

- Random variables X, Y, \dots
- Conditional probability $P(X=x|Y=y)$
 - Probability that X takes value x , given that $Y=y$

Information-theoretic security

◆ Cryptosystem is *info-theoretically secure* if

$$P(\text{Plaintext}=p | \text{Ciphertext}=c) = P(\text{Plaintext}=p)$$

H	Land	1
H	Sea	2
T	Land	2
T	Sea	1

◆ Ciphertext gives no info about plaintext

$\text{Prob}(1 \text{ is for Land}) = \text{Prob}(1 \text{ is for Sea})$
assuming that all keys are equally likely
