

## TCG: Trusted Computing Group

Dan Boneh

## Background

- TCG consortium. Founded in 1999 as TCPA.
  - Main players (promoters): (>200 members)  
AMD, HP, IBM, Infineon, Intel,  
Lenovo, Microsoft, Sun
- Goals:
  - **Hardware protected (encrypted) storage:**
    - + Only "authorized" software can decrypt data
    - + e.g.: protecting key for decrypting file system
  - **Secure boot:** method to "authorize" software
  - **Attestation:** Prove to remote server what software is running on my machine.

## TCG: changes to PC or cell phone

- Extra hardware: **TPM**
  - Trusted Platform Module (TPM) chip
    - + Single 33MHz clock.
  - TPM Chip vendors: (~7\$)
    - + Atmel, Infineon, National, STMicro
    - + Intel DB75GRH motherboard
- Software changes:
  - BIOS
  - OS and Apps

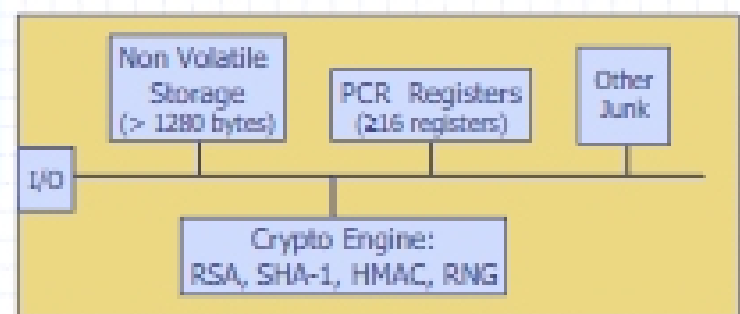

## TPMs in the real world

- Systems containing TPM chips:
  - Lenovo (IBM) Thinkpads and desktops
  - Fujitsu lifebook
  - HP desktop and notebooks
- Software using TPMs:
  - File/disk encryption: Vista, IBM, HP, Softex
  - Attestation for enterprise login: Cognizance, Wave
  - Client-side single sign on: IBM, Ultimaco, Wave

## TPM 101

- What the TPM does
- How to use it

## Components on TPM chip

RSA: 1024, 2048 bit modulus  
SHA-1: Outputs 20 byte digest

## PCR: the heart of the matter

- **PCR: Platform Configuration Registers**
  - Lots of PCR registers on chip (at least 16)
  - Register contents: 20-byte SHA-1 digest (←+junk)
- **Updating PCR #n :**
  - $TPM\_Extend(n,D): PCR[n] \leftarrow SHA-1(PCR[n] || D)$
  - $TPM\_PcrRead(n):$  returns value(PCR(n))
- **PCRs initialized to default value (e.g. 0) at boot time**
  - TPM can be told to restore PCR values via  $TPM\_SaveState$  and  $TPM\_Startup(ST\_STATE)$

## Using PCRs: the TCG boot process

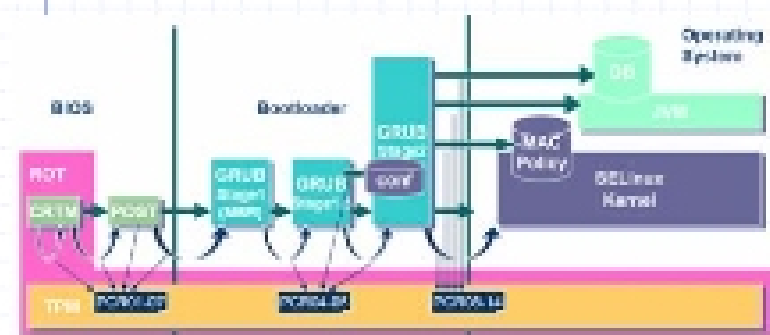

- At power-up PCR[n] initialized to 0
- BIOS boot block executes
  - Calls  $PCR\_Extend(n, <BIOS\ code>)$
  - Then loads and runs BIOS post boot code
- BIOS executes:
  - Calls  $PCR\_Extend(n, <MBR\ code>)$
  - Then runs MBR (master boot record), e.g. GRUB.
- MBR executes:
  - Calls  $PCR\_Extend(n, <OS\ loader\ code,\ config>)$
  - Then runs OS loader ... and so on

## In a diagram

- After boot, PCRs contain hash chain of booted software
- Collision resistance of SHA1 (?) ensures commitment

## Example: Trusted GRUB (IBM/OS)

What PCR # to use and what to measure specified in GRUB config file

## Using PCR values after boot

- **Application 1: encrypted (a.k.a sealed) storage.**
- **Step 1:  $TPM\_TakeOwnership(OwnerPassword, \dots)$** 
  - Creates 2048-bit RSA Storage Root Key (SRK) on TPM
  - Cannot run  $TPM\_TakeOwnership$  again:
    - + Ownership Enabled flag ← False
  - Done once by IT department or laptop owner.
- (optional) **Step 2:  $TPM\_CreateWrapKey$** 
  - Create more RSA keys on TPM certified by SRK
  - Each key identified by 32-bit keyhandle

## Protected Storage

- **Main Step: Encrypt data using RSA key on TPM**
  - $TPM\_Seal$  (some) Arguments:
    - +keyhandle: which TPM key to encrypt with
    - +KeyAuth: Password for using key 'keyhandle'
    - +PcrValues: PCRs to embed in encrypted blob
    - +data block: at most 256 bytes (2048 bits)
      - Used to encrypt symmetric key (e.g. AES)
  - Returns encrypted blob.
- **Main point: blob can only be decrypted with  $TPM\_Unseal$  when  $PCR\_req\_vals = PCR\_vals$  in blob.**
  - $TPM\_Unseal$  will fail otherwise

## Protected Storage

- Embedding PCR values in blob ensures that only certain apps can decrypt data.
  - e.g.: Messing with MBR or OS kernel will change PCR values.
- Why can't attacker disable TPM until after boot, then extend PCRs with whatever he wants?
  - Root of trust: BIOS boot block.
- Gaping hole: role-back attack on encrypted blobs
  - e.g. undo security patches without being noticed.
  - Can be mitigated using Data Integrity Regs (DIR)

## Sealed storage: applications

- Lock software on machine:
  - OS and apps sealed with MBR's PCR.
  - Any changes to MBR (to load other OS) will prevent locked software from loading.
  - Prevents reverse-engineering
- Web server: seal server's SSL private key
  - Goal: only unmodified Apache can access SSL key
  - Problem: updates to Apache, config, or content
- General problem with software patches:
  - When updating MBR, must re-seal blobs
  - Not a simple process ...

## TPM Counters

- TPM must support at least four hardware counters
  - Increment rate: every 5 seconds for 7 years.
- Applications:
  - Provides time stamps on blobs.
  - Supports "music will pay for 30 days" policy.

## Non-volatile TPM memory

- Stores:
  - Storage Root Key (SRK)
  - Owner Password

} Generated when user takes ownership

  - Endorsement Key (EK)
    - + Created once for the life of the TPM
    - + Certificate for EK issued by TPM vendor
    - + Basis of attestation
  - Persistent flags (e.g. ownership flag)

## Attestation

## Attestation: what it does

- Goal: prove to remote party what software is running on my machine.
- Good applications:
  - Bank allows money transfer only if customer's machine runs "up-to-date" OS patches.
  - Enterprise allows laptop to connect to its network only if laptop runs "authorized" software
  - Quake players can join a Quake network only if their Quake client is unmodified.
- DRM:
  - MusicStore sells content for authorized players only.
