

Translation and Proteins

- Translation (Protein synthesis)
 - In the late 1950s Paul Zamecnik and Mahlon Hoagland noticed that the RNA in particular cytoplasmic fraction became labeled with ^{14}C -amino acids and that the labeled RNA was subsequently able to transfer the amino acids to microsomal protein (rough ER)
 - Conclusion: the RNA later named transfer RNA or tRNA functions as an intermediate carrier of amino acids in protein synthesis
 - Zamecnik and Hoagland later contributed to our understanding of how transfer process works
 - Translation depends on mRNA rRNA and tRNA
 - Each codon (triplet) specifies one amino acid
 - To connect two languages Francis Crick proposed the 'adaptor hypothesis' in 1955 wherein 'transfer RNA' (tRNA) adapts each codon triplet in mRNA to the correct amino acid
 - Anticodon in tRNA pairs with codon of mRNA
 - Site of protein manufacture is the ribosome
 - Ribosome is most intricate of cell structures about 10,000 ribosomes/bacterial cell
 - ribosomes are made of *both* RNA and protein
 - differ between prokaryotes and eukaryotes

Prokaryotes Monosome 70S (2.5×10^6 Da)		Eukaryotes Monosome 80S (4.7×10^6 Da)	
Large subunit	Small subunit	Large subunit	Small subunit
50S 1.6×10^6 Da	30S 0.9×10^6 Da	60S 2.8×10^6 Da	40S 1.4×10^6 Da
 23S rRNA (2904 nucleotides) + 31 proteins + 5S rRNA (120 nucleotides)	 16S rRNA (1541 nucleotides) + 21 proteins	 28S rRNA (4718 nucleotides) + 46 proteins + 5S rRNA (120 nucleotides) + 5.8S rRNA (160 nucleotides)	 18S rRNA (1874 nucleotides) + 33 proteins

- Summary of differences between Prokaryotic and Eukaryotic Ribosomes
 - Prokaryotes
 - 50 S subunit
 - 23 S rRNA (2904 n)
 - 31 proteins
 - 5 S rRNA (120 n)
 - 30 S subunit
 - 16S rRNA (1541 n)
 - 21 proteins
 - One transcript produces 23S, 16S, and 5S rRNA 7 copies of gene in *E. coli*
 - Eukaryotes

- 60 subunit
 - 28 S rRNA (4718 n)
 - 49 proteins
 - 5 S rRNA (120 n)
 - 5.8 s rRNA (160 n)
- 40 S subunit
 - 18 S rRNA (1874 n)
 - 33 proteins
- One transcript produces 28S, 18S and 5.8 s rRNA 120 copies of gene in fly
- Transfer RNA (tRNA)
 - Small (about 83 nucleotides) stable RNA molecules
 - Cleaved from larger precursor RNA
 - Contain several modified nucleotides which are modified AFTER transcription (figure below)

- Cloverleaf model of tRNA

- Anticodon loop contains anticodon sequence
- The 3' end (pCpCpA) is where amino acid is covalently bound 5' Gp at end of every tRNA
- Shape of acceptor stem allows recognition by 'charging enzymes'
- 3-D model of tRNA

- Charging tRNA (loading the gun)

- Aminoacyl tRNA synthetases 'charge' a tRNA so it is covalently linked to its 'cognate amino acid'
- Could be 61 tRNAs but so far only about 32 know (other codons can be reorganized by same tRNA due to 'wobble' at 3rd position)
- Only about 20 synthetases needed in a given cell
